

Remarks

In view of the above amendments and the following remarks, reconsideration and further examination are requested.

The specification and abstract have been reviewed and revised to make a number of editorial revisions. A substitute specification and abstract have been prepared and are submitted herewith. No new matter has been added. Enclosed is a marked-up copy of the specification and abstract indicating the changes incorporated therein.

Claims 17, 23-28, 34 and 37 have been rejected under 35 U.S.C. §102(e) as being anticipated by Anvekar (US 2002/00686610).

It is noted that Anvekar was filed on December 5, 2000 and was published on June 6, 2002. It is also noted that the present application was filed on October 11, 2001 and claims priority to Japanese Application No. 2000-313151 which was filed on October 13, 2000, which is prior to the filing date of Anvekar. It is hereby submitted that the subject matter of claims 17, 23-28, 34 and 37 is fully supported by the priority document. Enclosed herewith is an English language translation of JP 2000-313151 including a statement verifying its accuracy. As a result, Anvekar is not eligible to be used as prior art against claims 17, 23-28, 34 and 37.

In view of the above amendments and remarks, it is submitted that the present application is now in condition for allowance. The Examiner is invited to contact the undersigned by telephone if it is felt that there are issues remaining which must be resolved before allowance of the application.

Respectfully submitted,

Kenji TAGAWA et al.

DESCRIPTION

Mobile Phone With Music Reproduction Function, Music
Data Reproduction Method by Mobile Phone With Music
5 Reproduction Function, and the Program Thereof

TECHNICAL FIELD

10 The present invention relates to a mobile phone with a music reproduction function, and especially relates to a mobile phone which is characterized by the operations at the time of receiving a call when a call arrives during reproducing music data, during a ~~talk~~ conversation, and after finishing a ~~talk~~ conversation.

BACKGROUND ART

15 A memory has been remarkably miniaturized and had larger capacity in recent years. In addition, as the audio compression technologies have been improved, new compression methods, such as MP3 (MPEG1 Audio Layer 3), have been suggested, wherein the quality of original sound in LPCM (Linear Pulse Code Modulation) is
20 not so deteriorated as to be ~~unfitted~~ unfit for comfortable listening even if it is compressed ~~into~~ to one tenth of the original ~~one~~ size. As these technologies have developed, it has been possible, for example, to record music data for one album on a stamp-sized semiconductor memory.

25 On the other hand, from the viewpoint of music distribution, in addition to the conventional distribution via package media, such as cassette tapes and CDs, there are indications that the form of directly downloading music data via Internet or the like (hereinafter referred to as "electronic music distribution") has been widely used.

30 In the electronic music distribution, as mentioned above, the form of downloading music data via the Internet using a personal computer (PC) is popular. However, since a PC ~~costs lots of initial~~ is

a relatively large investment, ~~other~~ distribution channels ~~other~~ than the PC-Internet have been considered, and among them, the form of downloading music data by using a mobile phone has attracted much attention. Although a mobile phone ~~has~~ now has problems of slow communication speed and high communication costs, it is expected that it can be one of the leading distribution channels if these problems are overcome by future improvement of communication technology. This is because mobile phones are very widely used and they ~~need~~ do not so much cost ~~of~~ as much as other equipments equipment required for electronic music distribution, such as PCs and others.

Fig. 1 is a diagram showing one example of a system of downloading/reproducing music data by using electronic music distribution. This music data downloading/reproducing system is comprised of a mobile phone 1101, a music reproduction player 1102 and a recording medium 1103. The mobile phone 1101, having a recording medium slot for inserting the after-mentioned recording medium 1103 in the body thereof, records the music data downloaded via Internet onto the recording medium 1103. The music reproduction player 1102, having a recording medium slot for inserting the recording medium 1103 therein, reads out and reproduces the music data recorded in the recording medium 1103. The recording medium 1103 is a portable memory, such as a semiconductor memory, and stores the music data recorded by the mobile phone 1101.

As shown in Fig. 1, if it is considered that the music data is downloaded by a mobile phone for listening to music, it may happen that after recording the downloaded music data onto the portable recording medium 1103, the recording medium 1103 is removed from the mobile phone 1101 and then inserted again into the music reproduction player 1102 for reproduction thereof. However, since carrying ~~about~~ both a mobile phone and a music reproduction device

on the way to the office and/or school means occupying ~~the~~ a space, such as a bag, with them, a mobile phone with music reproduction function, that is an integrated composite device having functions of both a mobile phone and a music reproduction device (hereinafter referred to as a mobile phone with music reproduction function) is desired.

As this kind of mobile phone with music reproduction function is just based on a phone, ~~the~~ processing which is not required for an ordinary music reproduction device is needed if a call arrives during reproducing music. For example, assuming that a call is received during listening to music by using a mobile phone with music reproduction function, it will be found that a mobile phone with music reproduction function has the following problems or challenges:

(1) Processing on receiving a call

An ordinary mobile phone informs a user of an incoming call by sound (a ring tone) outputted mainly from a speaker of the main body. However, a mobile phone with music reproduction function must notify a user of a ring tone without fault even while the user is listening to music through headphones. Particularly, if a melody tone is set to announce incoming calls, the music which the user is listening to must be clearly distinguished from the melody tone for incoming calls. In order to solve these problems, Japanese Laid-Open Patent Application H09-321844 discloses a portable communication device for outputting a ring tone by switching from music reproduction sound outputted from headphones, or outputting both a music reproduction sound and a ring tone by overlapping them, so as to notify a user of a ring tone when he/she receives a call during reproducing music.

This device is, however, uncomfortable and troublesome for a user, because reproducing music is suddenly switched into a ring tone on an unexpected timing, or abruptly overlapped with a ring

tone.

Also, it is desirable if the following processing is realized in addition to the above-mentioned processing on receiving a call.

(2) Processing During a Talk Conversation

Although it is generally desirable to stop reproducing music data during a talk conversation, it is considered that music reproduction need not always be stopped if a communicating partner over a phone is a close person like a family member.

(3) Reproduction Resume

When a music reproduction player temporarily stops music reproduction, it generally executes an operation of resuming music reproduction at the position of stopping reproduction. Compared with this kind of player for music reproduction only, a user's request for a mobile phone with music reproduction function may be quite different in that music reproduction is interrupted by receiving a call regardless of the user's will, that is, it is forced to be interrupted.

SUMMARY DISCLOSURE OF THE INVENTION

It is accordingly an object of the present invention, in the light of the above-mentioned conventional problems, to provide a more user-friendly mobile phone with music reproduction function without making a user feel uncomfortable by offering not only processing to solve problems which may arise when a call arrives during reproduction of music, but also various methods of music reproduction during a talk conversation and reproduction-resume resumption after finishing a talk conversation.

More specifically, the present invention has the following three objects. The first object of the present invention is to provide a mobile phone with music reproduction function that can surely inform a user of receiving a call without interrupting music reproduction suddenly when a call arrives during reproduction of music.

Also, the second object of the present invention is to provide a mobile phone with music reproduction function for a comfortable use that can convert the reproducing music into background music (BGM) during a ~~talk~~ conversation, or reproduce music which is preset for each communicating partner as BGM during a ~~talk~~ conversation.

Further, the third object of the present invention is to provide a mobile phone with sophisticated music reproduction function that has as many resume functions as a dedicated music reproduction player or more, in which, in the case of stopping reproduction of music on receiving a call, music reproduction is resumed at ~~the~~ a position run back for a predetermined time period from that of receiving ~~a~~ the call, or from the beginning of the music.

The above-mentioned first object may be achieved by a mobile phone with music reproduction function comprising: a reproduction unit that reproduces music data which is recorded in a recording medium, an incoming call detection unit operable to detect an incoming call from outside, a ring tone output unit operable to output a ring tone, and a control unit operable to instruct the reproduction unit to perform a fade-out process of reproducing music data and instructs the ring tone output unit to perform a fade-in process of outputting a ring tone when the incoming call detection unit detects an incoming call while the reproduction unit is reproducing music data.

As described above, in the mobile phone according to the present invention, the control unit instructs the reproduction unit to perform a fade-out process of reproducing music data and instructs the ring tone output unit to perform a fade-in process of outputting a ring tone when the incoming call detection unit detects an incoming call while the reproduction unit is reproducing music data.

In this way, according to the mobile phone of the present invention, since music is faded out and a ring tone is faded in after

a call arrives during reproduction of music, a user who is listening to music can easily catch a ring tone and perceives an incoming call without being confused by a sudden change of sound volume and music even when a call unexpectedly arrives during listening to music. As a result, there is an effect that a user can enjoy listening to music comfortably.

Here, the mobile phone may further comprise a unit operable to store information indicating per communicating partner whether or not to stop reproduction of music data when a call arrives during reproduction of music data. As a result, there is an effect that reproduction mode of music data may be changed depending upon a communicating partner. If a user has a business-~~talk~~ conversation or ~~makes~~ is making complicated arrangements, for example, reproduction of music data can be stopped after the music data is faded out so that the user can concentrate on his/her-~~talk~~ conversation.

Also, the mobile phone may further comprise a unit operable to count elapsed time after a call arrives, in which a ring tone is faded out and the music data which was being reproduced before a call arrives is faded in to be reproduced if a-~~talk~~ conversation does not start within a specified time elapsed after a call is detected. As a result, if a user has no will to respond to a call or will call back later by checking an incoming call record or the like of the mobile phone, he/she can leave the call as it is, and thus producing an effect that a user feels it convenient because he/she need not bother to operate the input unit in order to return to the condition before a call arrives. In addition, there is an effect that unnecessary battery consumption can be cut down.

Further, the mobile phone may start a fade-in process of a ring tone after a fade-out process of music data is completed. As a result, there is an effect that a user can clearly confirm an incoming call even if he/she uses a melody tone as a ring tone since the

reproduction sound of music data is not overlapped with the ring tone.

The above-mentioned second object may be achieved by a mobile phone with music reproduction function comprising: a reproduction unit operable to reproduce music data which is recorded in a recording medium, and a BGM unit operable to instruct the reproduction means to reproduce music data as background music in parallel with output of communicating voice.

As a result, a user can enjoy the music data stored in the recording medium as background music even during a talk conversation and further enjoy a lively and happy conversation with a partner.

Here, in the mobile phone, the BGM unit may instruct the reproduction unit to tune down the reproduction sound of music data to a specified sound volume. As a result, the sound volume of reproduction sound of music data is tuned down, and thus producing an effect that a user can easily hear communicating voice, such as talking voice and others.

Further, in the mobile phone, the BGM unit may instruct the reproduction unit to continue reproduction of music data when a talk conversation starts in response to a call when the call arrives while the reproduction unit is reproducing music data. As a result, there is an effect that a user can enjoy listening to music more comfortably because the music is not interrupted at an unexpected timing of receiving a call.

Further, in the mobile phone, the BGM unit may instruct the reproduction unit to continue reproduction of music data when a talk conversation starts in response to a call when the call is made to a communicating partner while the reproduction unit is reproducing music data. As a result, there is an effect that a user can enjoy music continuously during a talk even if the user himself/herself makes a call during reproduction of music data.

Also, the mobile phone may further comprise a BGM transmission unit operable to transmit the reproduction sound of music data reproduced by the reproduction unit in ~~answer~~ response to the instruction of the BGM unit to a communicating partner along with communicating voice. As a result, the communicating partner can also listen to the reproduction sound of music data as background music, and there is an effect that a user can enjoy an atmospheric conversation with the communicating partner.

Further, in the mobile phone, the BGM unit may instruct the reproduction unit to reproduce given music data as background music in parallel with output of communicating voice when a talk starts in response to a call after the call arrives while the reproduction unit is not reproducing music data. As a result, there is an effect that a user can enjoy given music data as background music during a ~~talk~~ conversation even if a call arrives while the music data is not being reproduced.

Further, in the mobile phone, communication processing information indicating per communicating partner whether or not to reproduce music data during a ~~talk~~ conversation may be stored, and the BGM unit may specify a communicating partner who is a caller when a call arrives and instruct the reproduction unit to reproduce given music data as background music during a ~~talk~~ conversation based on the communication processing information corresponding to the specified communicating partner. As a result, a user can choose reproduction or non-reproduction of background music during a ~~talk~~ conversation depending on a communicating partner. That is, there is an effect that a user can choose reproduction or non-reproduction of background music depending on a communicating partner in such a manner, for example, that given music data is reproduced as background music during a ~~talk~~ conversation with a close friend, a family member or the like and music data is not reproduced during a ~~talk~~ conversation with a boss,

a business partner or the like.

Further, in the mobile phone, a BGM data list indicating per communicating partner the file name of music data which should be reproduced as background music during a talk conversation after a call arrives while music data is not being reproduced may be stored, and the BGM unit may instruct the reproduction unit to reproduce the music data indicated in the BGM data list after a call arrives while music data is not being reproduced. As a result, there is an effect that since a user can select music data which should be reproduced as background music depending on a communicating partner, he/she can enjoy the music data for a communicating partner as background music. More specifically, since a user can select and transmit a communicating partner's favorite music data or music data to which a user wants the communicating partner to listen if background music is transmitted to the communicating partner along with communicating voice, there is an effect that a user can further develop a pleasure of a talk pleasurable conversation.

The above-mentioned third object may also be achieved by a mobile phone with music reproduction function comprising: a reproduction unit operable to reproduce music data which is recorded in a recording medium, a stop unit operable to temporarily stop reproduction by the reproduction unit, and a control unit operable to instruct the reproduction unit to reproduce music data based on a specified reproduction resume method after reproduction is stopped by the stop unit and then a talk conversation finishes. That is, the stop unit temporarily stops reproduction by the reproduction unit, and the control unit instructs the reproduction unit to reproduce music data based on a specified reproduction resume method after reproduction is stopped by the stop unit and then a talk conversation finishes.

As a result, since the music data is automatically reproduced

based on a specified reproduction resume method after reproduction is stopped and then a ~~talk~~ conversation finishes, there is an effect that a user can start listening to music again even after reproduction of music data is unexpectedly stopped and then a ~~talk~~ conversation finishes.

Further, the mobile phone may comprise a resume method storage unit operable to store information indicating a plurality of reproduction resume methods, wherein the control unit may select one of the reproduction resume methods and instruct the reproduction unit to reproduce music data based on the selected reproduction resume method. As a result, there is an effect that resume can be performed based on a variety of reproduction resume methods, thereby satisfying users' diversified needs.

Further, in the mobile phone, resume position information indicating one or more break points of music may be stored per music data, and the reproduction resume method may be a method to reproduce music data from the point indicated by the resume position information just before the point at which reproduction of the music data was stopped. As a result, since the music data is automatically reproduced from the break point of the music just before the point at which reproduction of the music data was stopped after the reproduction is stopped and then a ~~talk~~ conversation finishes, there is an effect that a user can resume listening to music more comfortably than when he/she resumes listening from ~~other~~ points other than the break point.

Further, in the mobile phone, the reproduction resume method designated by a user may be memorized, and the control unit may instruct the reproduction unit to reproduce music data based on the designated reproduction resume method. As a result, there is an effect that resume can be performed based on the reproduction resume method designated by a user, while a user can select and designate a reproduction resume method preferable to

himself/herself.

Further, the mobile phone may comprise an incoming call detection unit operable to detect an incoming call from outside, wherein the stop unit may instruct the reproduction unit to stop reproduction of music data when an incoming call is detected by the incoming call detection unit. As a result, since reproduction of music data is stopped when a call arrives, a user does not fail to catch a ring tone even during listening to music, and can talk in a clear communicating voice. In addition, there is an effect that after a talk finishes, a user can smoothly resume listening to music based on a specified reproduction resume method without any troublesome operations. Also, the present invention can be embodied as a music data reproduction method comprising steps for implementing the characteristic units included in the mobile phone, or as a program including the steps. Also, the program can, of course, be distributed via a recording medium, such as CD-ROM, or a communication network, such as the Internet.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other objects, advantages and features of the invention will become apparent from the following description thereof taken in conjunction with the accompanying drawings which illustrate a specific embodiment of the invention. In the Drawings:

Fig. 1 is a diagram that shows one example of a music data downloading/reproducing system by using electronic music distribution.

Fig. 2 is a diagram that shows the appearance of a ~~the~~ mobile phone 100 with music reproduction function of the present invention.

Fig. 3 is a functional block diagram that shows the structure of the mobile phone 100 with music reproduction function as shown in Fig. 2.

Fig. 4 is a diagram that shows one example of the data structure of digital music data which is recorded in the a music data recording medium 105 as shown in Fig. 3.

Fig. 5 is a diagram that shows the data structure of ~~the~~ information which is stored in the a incoming call processing information storage unit 107 as shown in Fig. 3.

Fig. 6 is a diagram that shows one example of ~~the~~ information which is stored in the a resume information storage area 303 as shown in Fig. 5.

Fig. 7 is a diagram that shows three examples of the resume methods among those which the mobile phone 100 with music reproduction function performs.

Fig. 8 is a diagram that shows by specific figures ~~the relations~~ relationships between ~~the~~ incoming call reproduction position information 312 which can be applicable for three types of resume patterns and the resume position information indicating an address of the reproduction resume position.

Fig. 9 is a diagram that shows one example of the method of specifying the resume position in relation to a variation example of the a resume pattern ② by using the an access point 208 in the music data recording medium 105 as shown in Fig. 3.

Fig. 10 is a flowchart that shows the operations of the control unit 103 when a call arrives during reproducing music data.

Fig. 11 is a flowchart that describes the operations of the a control unit 103 on resuming reproduction of music data after finishing a ~~talk~~ conversation if reproduction of music data is stopped when a call arrives.

Fig. 12 is a flowchart that shows the operations of the control unit 103 in the a case of receiving a call when music data is not being reproduced.

100 with music reproduction function if a user responds to a call within a time specified.

Fig. 13B is a timing chart that shows the sound volume transition of the ring tone of the mobile phone 100 with music reproduction function if a user responds to a call within a time specified.

Fig. 14A is a timing chart that shows the sound volume transition of the music data reproduction sound of the mobile phone 100 with music reproduction function if a user does not respond to a call within a time specified Δt .

Fig. 14B is a timing chart that shows the volume transition of the ring tone of the mobile phone 100 with music reproduction function if a user does not respond to a call within a time specified Δt .

DETAILED DESCRIPTION OF BEST MODE FOR CARRYING OUT THE INVENTION

The following is a detailed explanation of the structure of the mobile phone with music reproduction function according to one embodiment of the present invention with reference to figures. In the present embodiment, the explanation will be given on the assumption that the data subject to reproduction is limited to music data. Note that, however, the present invention is not limited to this embodiment, and may be embodied in combination of image data and music data, text data and music data, image and text data and music data, and others.

Fig. 2 is a diagram that shows the appearance of the a mobile phone 100 with music reproduction function of the present invention. The mobile phone 100 with music reproduction function of the present invention is typically a composite machine of a mobile phone and audio reproduction player, and can be used as a personal headset stereo as well as a phone. The mobile phone 100 with

music reproduction function is mainly comprised of a main body 1, controller 2, headphones 3, and a music data recording medium 105. The main body 1 is equipped with a liquid crystal display panel 4, a ten key unit 5, a speaker 6, a microphone 7, a recording medium slot 8, a music reproduction control key unit 9, a phone control key unit 10, an antenna 11 and others. The controller 2 is equipped with a liquid crystal display panel 12 and a music reproduction control key unit 13 and others. The headphones 3 are speakers which output music data reproduction sound, a ring tone, partner's voice and others through the ear pad unit thereof and which a user wears over his/her ears.

The liquid crystal display panel 4 displays the contents regarding a mobile phone, such as a phone number which a user inputs by operating the after-mentioned ten key unit 5, a caller's phone number on receiving a call, phone book data which a user registers, setting of each function, a note, a text of e-mail, and a Web page, as well as the contents regarding a music reproduction player, such as a title of reproducing music data, music data reproducing order and a music data reproducing mode.

The ten key unit 5 is a unit for inputting keys indicating figures, characters, symbols and cursor movement by which a user inputs a phone number and a text of an e-mail or sets a reproduction mode of music data. The speaker 6 outputs reproduction sound of music data, a ring tone, a communicating partner's voice and others. The microphone 7 inputs a user's voice.

The recording medium slot 8 is an inserting slot for connecting the music data recording medium 105 to the main body 1. The music reproduction control key unit 9 is a key input unit which is equipped with a sound volume button and buttons for various functions of a music reproduction player, such as music data reproduction start, rewind, fast-forward, reproduction stop, and mode settings. The phone control key unit 10 is a key input unit

which is equipped with buttons for various functions of a mobile phone, such as calling, talking, holding, cutting the line, connecting with the Internet, and cutting off the power. The antenna 11 transmits and receives a radio wave of mobile phone communication.

The liquid crystal display panel 12 mainly displays the abbreviated contents regarding music data reproduction. The music reproduction control key unit 13 is equipped with a sound volume button and buttons for various functions of a music reproduction player, such as music data reproduction start, rewind, fast-forward, reproduction stop and mode settings.

Fig. 3 is a functional block diagram that shows the structure of the mobile phone 100 with music reproduction function as shown in Fig. 2. The mobile phone 100 with music reproduction function of the present invention is, as shown in Fig. 3, equipped with an input unit 101, a display unit 102, a control unit 103, a music data readout unit 104, a the music data recording medium 105, a reproduction unit 106, an incoming call processing information storage unit 107, a communication unit 108, a ring tone readout unit 109 and a ring tone storage unit 110. These component elements will be explained below.

The input unit 101, which is equivalent to an operation unit such as the ten key unit 5, the music reproduction control key unit 9, the phone control key unit 10 and the music reproduction control key unit 13, and a voice sound input unit, such as the microphone 7, accepts the input of a user's instructions by his/her operating the above-mentioned operation unit. User's instructions include, for example, an instruction to accept the input of the communicating partner's phone number to make a call, a reproduction start instruction to start music reproduction, a stop instruction to stop music reproduction, a fast-forward instruction to fast-forward music reproduction and a rewind instruction to rewind music reproduction.

The display unit 102, which is the liquid crystal display panel 4 and the liquid crystal display panel 12 as shown in Fig. 2, displays a phone number of which input was accepted by the input unit 101 and a title of the reproducing music.

5 The control unit 103, which is typically equipped with a CPU, a ROM/RAM and others, controls each unit of the mobile phone 100 with music reproduction function by executing the programs stored in the ROM. This means, for example, the control unit 103 interprets a user's instruction of inputting a phone number via the
10 input unit 101, instructs the communication unit 108 to make a call, and instructs the display unit 102 to display the phone number inputted by a user. Also, if a user instructs to reproduce music via the input unit 101, ~~it~~ the control unit 103 instructs to read out music data to the after-mentioned music data readout unit 104.

15 Further, when a call arrives, the control unit 103 executes a specified incoming call processing depending on the incoming call processing methods stored in the after-mentioned incoming call processing information storage unit 107. For example, if music is
| being reproduced when a call arrives, ~~it~~ the control unit 103
20 instructs the after-mentioned ring tone readout unit 109 to read out the ring tone stored in the after-mentioned ring tone storage unit 110, instructs the after-mentioned reproduction unit 106 to start fading out the reproducing music and fading in the ring tone, and instructs the after-mentioned music data readout unit 104 to stop
25 reading out the music data after finishing fade-out.

 In addition, if music data has been reproduced and reproduction thereof is stopped at the time of receiving a call, the control unit 103 instructs the music data readout unit 104 to read out the music data from a specified reproduction starting position
30 based on the resume method stored in the incoming call processing information storage unit 107 when a ~~talk~~ conversation finishes.

 The music data readout unit 104 records the music data,

image data, text data or the like downloaded by the after-mentioned communication unit 108 in the after-mentioned music data recording medium 105, as well as reads out the music data and others recorded in the music data recording medium 105 based on the instruction by the control unit 103 to read out music data.

The music data recording medium 105 is typically a small-sized portable read/write recording medium comprised of a semiconductor memory and others, and the music data downloaded from the Internet and others via the after-mentioned communication unit 108 is, for example, recorded therein.

The music data recording medium 105 has a sector structure. Each sector stores digital data of 512-byte bytes according to the present embodiment. The music data recording medium 105 stores file system information for managing multiple sectors as a file in the predetermined sectors. The file system applied for the music data recording medium 105 is based on the file system prescribed under ISO9293. Note that the music data recording medium 105 need not always be removable from the mobile phone 100 with music reproduction function of the present invention, and may be built in the mobile phone 100 with music reproduction function.

The reproduction unit 106, which is equipped with an MPEG decoder, a D/A converter, a sound volume controlling circuit and a speaker, reproduces music data, a ring tone and communicating voice/sound. It decodes, makes D/A conversion of, and reproduces the music data which the music data readout unit 104 reads out from the music data recording medium 105. The decoded music can be listened to over headphones or the like. Also, the reproduction unit 106 has a sound volume controlling function, such as fade-in and fade-out.

The incoming call processing information storage unit 107 is typically an EEPROM (Electrically Erasable Programmable Read-Only Memory), and a memory that stores a communicating partner's

phone number, ring tone reproduction methods when a call arrives, and information of resume of music data reproduction after finishing a ~~talk~~ conversation. More specifically as to resume of music data reproduction, the incoming call processing information storage unit 5 107 is a memory in which the file name and position information of the music data which the reproduction unit 106 was reproducing, and the resume method (or the information for identifying the resume method) indicating at which position of the music data reproduction is to be resumed are stored when the control unit 103 10 instructs the reproduction unit 106 to stop music data reproduction. The control unit 103 refers to this information when it resumes music data reproduction, identifies appropriate music data and a specific readout position thereof, and instructs the music data readout unit 104 to readout the music data.

15 Also, the incoming call processing information storage unit 107 stores the phone book registered by the user of the mobile phone 100 with music reproduction function. ~~It~~ The incoming call processing information storage unit 107 also stores the contents set by the user of the processing method on receiving a call per 20 communicating partner which the user designates corresponding to the phone book.

The communication unit 108 includes an antenna, a wireless transmission/reception unit and a communication interface which communicate with base stations by wireless. Also, the 25 communication unit 108 informs the control unit 103 of start/finish of communication-related processes, such as receiving a call, and start and finish of a ~~talk~~ conversation.

The ring tone readout unit 109 reads out a ring tone from the after-mentioned ring tone storage unit 110, in response to the 30 instruction from the control unit 103 of reading out a ring tone.

The ring tone storage unit 110 is a recording medium in which ring tones are stored. The ring tones which can be recorded therein

are not limited to one, in other words, more than one ring tone may be recorded. In this case, the ring tone which is to be read out may be preset, or selected at random.

Fig. 4 is a diagram that shows one example of the data structure of digital music data which is recorded in the music data recording medium 105 as shown in Fig. 3. As shown in Fig. 4, the music data recording medium 105 is comprised of a song data storage area 201 in which the music data is stored per song in a file format, and a reproduction path management area 202 in which reproduction path information that defines the reproduction order of the music data is stored.

The song data storage area 201 is an area in which N song data 203, recorded in an MPEG2-AAC (Advanced Audio Coding) format, for example, is stored per song in a file format. Note that $0 \leq N \leq 999$ song data, that is, a maximum of 999 song data can be stored in the song data storage area 201.

On the other hand, the reproduction path management area 202 is an area in which the reproduction path information, that is, the information that defines reproduction order of the song data 203 recorded in the song data storage area 201 is stored. Reproduction path information is comprised of a number of melodies 204 indicating the number of the song data 203 recorded in the song data storage area 201, and reproduction control information 205 of each song data 203 recorded in the song data storage area 201.

The number of melodies 204 is the information indicating the number N of the song data 203 stored in the song data storage area 201, that is, the number of music data recorded in the music data recording medium 105, and $0 \leq N \leq 999$, that is, a maximum of 999 melodies can be recorded according to the present embodiment, as described above in the explanation of the song data 203.

The reproduction control information 205 is comprised of a file name 206 indicating the file name of the song data 203, a

number of access points 207 indicating ~~the~~ a number M of the access points which can be selected for a reproduction resume position of the song data 203 when music reproduction is resumed as described later, and access points 208 indicating the address position of each
5 access point. Note that the number of access points 207 is $0 \leq M \leq 99$, that is, 99 at maximum.

It is also noted that ~~By the way,~~ the music data recording medium 105 is equipped with a so-called FAT (File Allocation Table) file system prescribed under ISO9293 as described before, and can
10 identify the ~~said~~ file based on the file name described in the file name 206 so as to specify the recording start address and recording end address of the song data 203 based on the information of the FAT table.

Further, in reproducing music, the song data 203 is
15 reproduced in the order described in the reproduction control information 205. For example, if the song data #1 is described in the reproduction control information #1, the song data #3 in the reproduction control information #2, and the song data #2 in the reproduction control information #3, respectively, the song data is
20 reproduced in the order of data #1, #3 and #2.

As mentioned above, according to the data structure of the music data recording medium 105 as shown in Fig. 4, music data itself can be stored in the music data recording medium 105, and, at the same time, the reproduction order thereof can be defined by the
25 reproduction path information stored in the reproduction path management area 202.

Fig. 5 is a diagram that shows the data structure of the information which is stored in the incoming call processing information storage unit 107 as shown in Fig. 3. As shown in Fig. 5,
30 the incoming call processing information storage unit 107 is comprised of a phone book storage area 301, an incoming call processing method storage area 302, a resume information storage

area 303 and resume method storage area 304.

The phone book storage area 301 is an area in which a user of the mobile phone 100 with music reproduction function of the present invention registers the communicating partners' phone numbers and names by operating the input unit 101. The phone book storage area 301 is comprised of a number of registrants 305 indicating ~~the~~ a number L of the registered communicating partners, and a registrant 306 indicating the information of registered communicating partners.

The number of registrants 305 is the information indicating how many registrants' data are registered in the phone book storage area 301, and $0 \leq L \leq 99$, that is, a maximum of 99 registrants can be registered.

The registrant 306 is further comprised of a registrant name 307, a phone number 308, an incoming call processing method 309 and a BGM file name 310.

The registrant name 307 describes the names which the user of the mobile phone 100 with music reproduction function inputs when he/she registers the communicating partners in the phone book storage area 301. The phone number 308 describes the phone numbers of the communicating partners whose names are written in the registrant name 307. The incoming call processing method 309 is the information indicating the processing method on receiving a call per registrant (communicating partner over a phone) whose name is written in the registrant name 307, and if music reproduction is stopped on receiving a call and a ring tone is reproduced, for example, "1" is written. If music is reproduced as BGM during a ~~talk~~ conversation without stopping reproduction thereof on receiving a call, "2" is written. The BGM file name 310 stores the file name of the music data that is to be reproduced as BGM during a ~~talk~~ conversation if a call arrives from the registrant whose name is written in the registrant name 307 while music data

is not being reproduced. If a file name of the music data that is to be reproduced as BGM is not specified, "0" is written.

Note that, according to the present embodiment, when the incoming call processing method 309 is "2" and a call arrives during reproducing music data, the reproducing music data is continued to be reproduced as BGM without stopping it. Also, when the incoming call processing method 309 is "2" and a call arrives while music data is not being reproduced, the music data having the file name written in the BGM file name 310 is reproduced as BGM. The present invention is not, of course, limited to this embodiment, but if a call arrives during reproducing music data and when the incoming call processing method 309 is "2", for example, reproduction of music data can be stopped once so as to reproduce the music data having the file name written in the BGM file name 310.

Next, the incoming call processing method storage area 302 is an area in which a processing method on receiving a call for a caller who is not registered in the phone book storage area 301 is stored. The processing method on receiving a call is as follows. If reproduction of music data is stopped and a ring tone is reproduced when a call arrives during reproducing music data, "1" is written. If reproduction of music data is not stopped when a call arrives and music data is reproduced as BGM during a ~~talk~~ conversation, "2" is written.

Note that an area for storing a file name of music data for BGM, such as the BGM file name 310, is not set up in the incoming call processing method storage area 302. Therefore, when a call arrives while music data is not being reproduced even if "2" is stored in the incoming call processing method storage area 302, music data is not reproduced as BGM for a caller who is not registered in the phone book storage area 301. The present invention is not limited to this embodiment, of course, but music data can also be

reproduced as BGM during a talk for a caller who is not registered in the phone book storage area 301, by setting up in the incoming call processing method storage area 302 an area for storing the file name of music data which is to be reproduced as BGM during a talk
5 for a caller who is not registered in the phone book storage area 301 so as to describe the file name of music data which is to be reproduced as BGM during a ~~talk~~ conversation as it is written in the BGM file name 310.

The resume information storage area 303 is comprised of the
10 resume file name 311 and the incoming call reproduction position information 312.

The resume file name 311 describes the file name of music data which is being reproduced when the control unit 103 instructs to stop reproduction thereof, if a user of the mobile phone 100 with
15 music reproduction function is reproducing music data when a call arrives. On the other hand, if music data is being reproduced when a call arrives, the incoming call reproduction position information 312 describes address information indicating the reproduction position of music data at the point of time when the control unit 103
20 instructs the reproduction unit 106 to stop reproduction thereof.

Fig. 6 is a diagram that shows one example of the information which is stored in the resume information storage area 303 as shown in Fig. 5. The resume information storage area 303 stores a resume file name 401 and incoming call reproduction position
25 information 402. In the resume file name 401, the file name "Song01.aac" of the music data is written which is being reproduced when a call arrives, that is, when the control unit 103 instructs the reproduction unit 106 to stop reproducing the music data. On the other hand, in the incoming call reproduction position information
30 402, the reproduction position of the file, which is being reproduced when a call arrives, that is, when the control unit 103 instructs the reproduction unit 106 to stop reproducing the music data, is written

as byte number from the beginning of the file, "1234", for example. It is possible to specify the file of the music data which is being reproduced when a call arrives and the reproduction position thereof according to the information.

5 The resume method storage area 304 is an area in which the number corresponding to the resume patterns indicating a plurality of types of resume methods is stored. Music data reproduction is resumed according to the ~~said~~ resume methods if a user of the mobile phone 100 with music reproduction function is reproducing
10 music data when a call arrives and stops reproducing music data during a ~~talk~~ conversation. There are three types of resume patterns: ~~1~~ resume pattern ① of resuming reproduction at the position of stopping thereof after finishing a ~~talk~~ conversation; resume pattern ② of resuming reproduction at the position
15 rewound for a specified time of seconds from the position of stopping reproduction; ~~and~~ and resume pattern ③ of resuming reproduction from the beginning of the music, and they are stored in the resume method storage area 304 as numbers "1", "2" and "3", respectively.

20 Note that, although, in the case of resume pattern ② of resuming reproduction at the position which is rewound for a specified time of seconds, a fixed value of rewinding time, for example, 5 seconds or 3 seconds is stored in a ROM, the mobile phone 100 with music reproduction function of the present invention
25 is not limited to this embodiment. An area for storing rewinding time of seconds from the position of stopping reproduction can be set up further in the resume method storage area 304, for example, so as to store the time inputted by a user therein. Further, in the case of resume pattern ②, if a call time during stopping reproducing
30 music data is counted and is beyond a specified threshold, the resume pattern ③ may be uniformly applied even if "2" is stored in the resume method storage area 304, so as to resume reproducing

music data from the beginning of a melody of the music data.

Fig. 7 is a diagram that shows three examples of the resume methods among those which the mobile phone 100 with music reproduction function performs. In Fig. 7, assume that the song data 203 is being reproduced from a song beginning 501, the communication unit 108 detects receipt of a call at the position shown as a incoming call point 503, and the control unit 103 instructs the reproduction unit 106 to stop reproducing music data. In Fig. 7, according to the resume method as shown in the resume pattern ①, reproduction is resumed at an address stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107. Next, according to the resume method as shown in the resume pattern ②, reproduction is resumed at a resume position 502 which is run back for a specified value from an address stored in the incoming call reproduction position information 312. Here, running back for a specified value means resuming reproduction at the point run back for 5 seconds, for example, from the point of reproduction on receiving a call. Note that, in order to run back for a specified value, it is necessary in reproduction to store addresses per second, for example, in a RAM from the beginning of the file and calculate an appropriate address at which reproduction is resumed based thereon.

Finally, according to the resume pattern ③, regardless of an address value stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107, reproduction is resumed from the song beginning 501. Fig. 8 describes specific figures indicating the resume positions according to these three types of resume methods.

Fig. 8 is a diagram that shows by specific figures the relations between the incoming call reproduction position information 312 which can be applicable for three types of resume patterns and the

resume position information indicating an address of the reproduction resume position. In Fig. 8, a resume pattern 601 shows three types of resume patterns as shown in Fig. 7. Incoming call reproduction position information 602 shows address information from the beginning of the file of the song data 203 which is being reproduced when a call arrives. Each information stored in resume position information 603 indicates at which position of the song data 203 the reproduction is resumed among ~~3~~ three types of resume methods. Further, assume that the address which is stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107 is "1234". In this case, according to the resume pattern ①, the address as resume position information is also "1234", since reproduction is resumed at the reproduction position at the point of receiving a call. Next, according to the resume pattern ②, the resume position is run back for a specified value from the reproduction position at the point of receiving a call, 5 seconds for reproduction, for example. "765" indicates the address value which is run back for the ~~said~~ specified value from "1234". Lastly, according to the resume pattern ③, the address as resume position information is "0" since reproduction is resumed from the song beginning 501.

As described above, according to the mobile phone 100 with music reproduction function of the present invention, three types of resume patterns ①~③ of the resume pattern 601 can be provided, thereby producing an effect that a user can choose and perform a resume method preferable for himself/herself among the above-mentioned methods ①~③.

Fig. 9 is a diagram that shows one example of the method of specifying the resume position in relation to a variation example of the resume pattern ② by using the access point 208 in the music data recording medium 105 as shown in Fig. 3. For example, points which seem to be preferable for a user to resume reproduction such

as the beginning of the first chorus, the beginning of the second chorus or each passage are stored beforehand in the access point 208. According to the present embodiment, 4 access points, first access point 704, second access point 705, third access point 706 and fourth access point 707 are registered therein. In Fig. 9, the top arrow indicates that the reproduction unit 106 reproduces the song data 203 from the song beginning 701, the communication unit 108 detects receipt of a call at the position shown as a first incoming call point 702, and the control unit 103 indicates the reproduction unit 106 to stop reproducing music data. The second arrow from the top indicates that the control unit 103 instructs the reproduction unit 106 to run back to the first access point 704 just before the first incoming call point 702 so as to resume reproduction thereat.

On the other hand, the third arrow from the top indicates that the reproduction unit 106 reproduces the song data 203 from the song beginning 701, the communication unit 108 detects receipt of a call at the position shown as a second incoming call point 703, and the control unit 103 instructs the reproduction unit 106 to stop reproducing the song data 203. Further, the fourth arrow from the top indicates that the control unit 103 runs back to the third access point 706 just before the second incoming call point 703 so as to resume reproduction thereat.

Note that, if there is no access point just before the incoming call point, the control unit 103 resumes reproduction from the song beginning 701. Further, a user can modify or add to the said access point 208 which is registered depending on the song data 203 by providing the mobile phone 100 with music reproduction function with an editing function.

As described before, according to the above-mentioned variation example, the access point 208 is determined which is possible to be chosen for the resume position depending on the contents of song data 203, and therefore, a user can decide more

meaningful resume position than that decided based on the address information meaningless for a user who listens to music. Further, there is an effect that a variety of resume methods can be realized flexibly at a user's request by setting such a variety of resume patterns.

Next, the operations of the mobile phone 100 with music reproduction function as structured above are explained below by using flowcharts of Fig. 10~Fig. 12 and timing charts of Fig. 13A~Fig. 14B.

Fig. 10 is a flowchart that shows the operations of the control unit 103 when a call arrives during reproducing music data. The control unit 103 waits for a notice of receiving a call from the communication unit 108 during reproducing music data in the reproduction unit 106 (S801). If the control unit 103 receives a notice of receiving a call from the communication unit 108, it examines whether a caller's phone number is stored in the phone book storage area 301 of the incoming call processing information storage unit 107, and determines whether the caller has been already registered in the phone book storage area 301 (S802). If the caller ~~has been~~ already has been registered as a result of the determination, the control unit 103 reads out the incoming call processing method stored in the incoming call processing method 309 (S803). On the other hand, if the caller has not registered in the phone book storage area 301, as a result of determination of Step S802, the control unit 103 reads out the incoming call processing method stored in the incoming call processing method storage area 302 (S805).

Then, the control unit 103 determines, based on the read-out incoming call processing method, whether to stop reproducing music data or continue reproducing music data as BGM (S804). If the control unit 103 determines to stop reproducing music data, it has the reproduction unit 106 start fade-out processing of music

data reproduction, and at the same time, has the ring tone readout unit 109 read out a predetermined ring tone from the ring tone storage unit 110, and has the reproduction unit 106 start fade-in processing of the read-out ring tone so as to reproduce the ring tone by mixing it with the reproduction sound of music data (S807).

Further, the control unit 103 has the reproduction unit 106 stop reproducing music data (S808), records the file name 206 of reproducing music data in the resume file name 311 of the resume information storage area 303 within the incoming call processing information storage unit 107 and the address information of the point of stopping reproduction, that is, the resume position information in the incoming call reproduction position information 312 of the resume information storage area 303 (S809), and then, shifts to Step S810.

If the control unit 103 determines to continue reproducing music data as BGM in Step S804, it has the reproduction unit 106 tune down gradually the sound volume of the reproducing music data to that for BGM reproduction. At the same time, it has the ring tone readout unit 109 read out the predetermined ring tone from the ring tone storage unit 110, has the reproduction unit 106 start fade-in processing of the read-out ring tone, so as to reproduce the ring tone by mixing it with the BGM reproduction sound (S806), starts counting the time elapsed from the point when the ring tone starts reproducing, and waits for the notice of starting communication from the communication unit 108 (S810).

The control unit 103 counts the time elapsed from the point when the ring tone starts reproducing, determines whether the communication unit 108 gives notice of starting communication before the said counted elapsed time goes beyond a predetermined time, thereby determining whether or not a user responded to a call within a predetermined time (S811). If the user responded to a call within a predetermined time, the control unit 103 finishes the

process. On the other hand, if the user did not respond to a call within a predetermined time, it has the reproduction unit 106 stop reproducing the ring tone assuming that the user has no will to respond to a call (S812), resumes reproduction of music data if the reproduction thereof is stopped, and returns the sound volume of music data to the ordinary volume (in a call waiting mode) if the music data is being reproduced as BGM, so as to complete the processing.

Note that in the present embodiment, the control unit 103 has the reproduction unit 106 perform the process of fading in a ring tone so as to reproduce it mixed with the reproduction sound of music data or BGM. It is not always necessary to mix the ring tone with the reproduction sound of music data, and the ring tone may be reproduced from the right (or left) side speaker of the headphones 3 and the reproduction sound of music data may be reproduced from the left (or right) side speaker thereof, for example.

Since the mobile phone 100 with music reproduction function according to the above-mentioned embodiment determines whether to stop reproduction of reproducing music data or to continue reproduction thereof as BGM depending on the incoming call processing method stored in the incoming call processing method 309 for the registered communicating partner, it has an effect that a user can have choice to concentrate on his/her talk by stopping reproduction of music depending on a communicating partner, or to enjoy BGM with him/her. Also, since the mobile phone 100 with music reproduction function determines above-mentioned incoming call processing for a non-registered partner, depending on the incoming call processing methods stored in the incoming call processing method storage area 302, it can be set even for a partner who does not communicate so often whether to stop reproduction of reproducing music or to continue reproduction, though uniformly. Further, the mobile phone 100 with music reproduction function

automatically stops reproduction of ring tone if a user does not respond to a call within a specified period from a point of receiving a call, it has an effect that consumption of a battery by reproduction of a ring tone is cut down. In this case, if oscillation by a vibrator as well as reproduction of ring tone is used in order to inform an incoming call, the vibrator may be stopped at the same time of stopping the ring tone, thereby producing an effect particularly in terms of cutting down consumption of a battery.

Fig. 11 is a flowchart that describes the operations of the control unit 103 on resuming reproduction of music data after finishing a talk conversation if reproduction of music data is stopped when receiving a call.

The control unit 103 waits for a notice of finishing a talk conversation from the communication unit 108 (S901). If there is a notice of finishing a talk conversation, it determines the resume method for resuming reproduction of music data. Here, the resume method is based on the assignment of resume patterns stored in the resume method storage area 304 within the incoming call processing information storage unit 107 (S902). If "1" is stored in the resume method storage area 304, for example, the resume pattern ① is specified.

Next, music data which should be reproduced in the resume method determined in Step S902 is specified. The music data which should be reproduced is specified by the resume file name 311 of the resume information storage area 303 within the incoming call processing information storage unit 107. Further, the control unit 103 specifies the resume position of specified music data. According to the resume pattern ①, for example, it specifies the address which is stored in the incoming call reproduction position information 312 of the incoming call processing information storage unit 107. Next, the control unit 103 instructs the music data readout unit 104 to read out music data from the specified resume

position (S903).

Further, the control unit 103 instructs the reproduction unit 106 to reproduce the music data read out by the music data readout unit 104 so as to complete the processing (S904). In response to this instruction, the reproduction unit 106 reproduces music data from the resume position specified in Step S903.

As described above, according to the present embodiment, the mobile phone 100 with music reproduction function resumes reproduction of interrupted music data according to the resume pattern stored in the resume method storage area 304, thereby producing an effect that after finishing a talk conversation, the music data can be reproduced according to the preferred resume pattern which a user selected beforehand even if the reproduction of music is interrupted at a timing unexpected for a user.

Fig. 12 is a flowchart that shows the operations of the control unit 103 in the case of receiving a call when music data is not being reproduced.

The control unit 103 waits for a notice of receiving a call from the communication unit 108 (S1001). If there is a notice of receiving a call, the control unit 103 examines whether a caller's phone number is registered in the phone number storage area 301 of the incoming call processing information storage unit 107 to determine whether the caller has already been registered in the phone number storage area 301 (S1002). If it is found, as the result of the determination, that the caller is not registered in the phone book storage area 301, the control unit 103 completes the processing.

If it is found, as the result of the determination, that the caller is registered, the control unit 103 reads out the BGM file name 310 for the corresponding registrant 306 within the incoming call processing information storage unit 107 (S1003).

Next, the control unit 103 determines whether the file name is

specified or not based on the contents of the read-out BGM file name 310 (S1004). If the content of the read-out BGM file name 310 is "0", for example, it indicates that the file name is not registered, and if the content of the read-out BGM file name 310 is not "0", it is the
5 file name of the music data. The control unit 103 completes the processing, if the file name is not specified as the result of determination in Step S1004.

If the file name is specified as the result of determination in Step S1004, the control unit 103 waits for a notice of starting
10 communication from the communication unit 108 (S1005). When it receives the notice of starting communication from the communication unit 108, it instructs the music data readout unit 104 to read out music data specified in the BGM file name 310, and starts a process of reproducing music data as BGM by instructing the
15 reproduction unit 106 to reproduce the read-out music data as BGM (S1006), thereby completing the processing.

As described above, according to the present embodiment, the mobile phone 100 with music reproduction function can reproduce music data as BGM even if a call arrives while music data
20 is not being reproduced. Further, the mobile phone 100 with music data reproduction function can reproduce the music data specified by a user in the BGM file name 310 as BGM, thereby producing an effect that both a user and his/her communicating partner can enjoy listening to the music data as BGM by selecting the music data
25 corresponding to the partner for the BGM file name 310, such as his/her favorite song.

Fig. 13 A is a timing chart that shows the sound volume transition of the music data reproduction sound of the mobile phone 100 with music reproduction function if a user responds to a call
30 within a time specified. Fig. 13 B is a timing chart that shows the sound volume transition of the ring tone of the mobile phone 100 with music reproduction function if a user responds to a call within a

time specified. In Fig. 13 A, the sound volume transition as shown in a full (solid) line LA1 indicates the case (1) where a user is reproducing music data when a call arrives and "1" is stored in the incoming call processing method 309 or the incoming call processing method storage area 302 in Fig. 5. The sound volume transition as shown in a dotted line LA2 indicates the case (2) where a user is reproducing music data when a call arrives and "2" is stored in the incoming call processing method 309 or the incoming call processing method storage area 302 in Fig. 5. The sound volume transition as shown in a dashed line LA3 indicates the case (3) where a user is not reproducing music data when a call arrives and "2" is stored in the incoming call processing method 309 in Fig. 5 and the music data is specified in the BGM file name 310. Both Fig. 13A and Fig. 13B indicate the sound volume v on the vertical axis and time t on the horizontal axis.

In the above-mentioned case (1), as shown in a the full line LA1, when a user receives a call at a time $t = t_1$ during reproducing music data in volume $v = v_1$ (in Step 801 of Fig. 10), the control unit 103 checks the caller's phone number with the phone number 308 of each of the registrant 306 in the phone number storage area 301 of the incoming call processing information storage unit 107 (Step S802). If they match each other, it reads out the incoming call processing method 309 of the registrant 306 (Step S803), and if they don't match, it reads out the incoming processing method in the incoming processing method storage area 302 (Step S805). If the incoming call processing method "1" is read out (Step S804), the control unit 103 instructs the reproduction unit 106 to fade out the reproduction of music data, instructs the ring tone readout unit 109 to read out the ring tone from the ring tone storage unit 110, and at the same time, instructs the reproduction unit 106 to fade in the reproduction of the read-out ring tone (Step S807). Thereby, the reproduction sound volume of music data v is faded out from v_1 to

0 during the time of $t_1 \leq t \leq t_2$ as shown in ~~a~~ the full line LA1, and at the same time, the sound volume of ring tone is faded in from 0 to v_3 during the time of $t_1 \leq t \leq t_2$ as shown in Fig. 13B. Next, after finishing the fade-out processing, the control unit 103 instructs the reproduction unit 106 to stop reproducing music data (Step S808), and records the resume file name 311 and the incoming call reproduction position information 312 (Step S809). Thereby, reproduction of music data is stopped ($v = 0$) after the time of $t = t_2$ has passed as shown in ~~a~~ the full line LA1, and at the same time, only the ring tone is reproduced at a constant level of sound volume v_3 as shown in Fig. 13B. Here, when a user responds to a call by operating the input unit 101 or the like ($t = t_3$) (Step S811), the communication unit 108 stops the processing of reading out the ring tone by the ring tone readout unit 109 so as to start communication. Thereby, the ring tone is stopped at the time of $t = t_3$ as shown in Fig. 13B, and only the communicating voice/sound is outputted until finishing a ~~talk~~ conversation.

Note that here that although the reproduction sound of music data is faded out and the ring tone is faded in at the same timings t_1 and t_2 of starting and finishing thereof, the reproduction sound of music data can be faded out and the ring tone ~~is~~ can be faded in at a different timings. For example, the timing of starting fade-out of the reproduction sound of music data may be later than that of starting fade-in of the ring tone, and the timing of finishing fade-in of the ring tone may be earlier than that of finishing fade-out of the reproduction sound of music data, and vice versa. Also, the fade-out speed of reproduction sound of music data may be faster than the fade-in speed of ring tone, and vice versa. Further, a user can adjust the fade-in/fade-out timings and speed. In addition, although the ring tone is stopped at the time of $t = t_3$ by starting communication, the ring tone can be ~~fade~~ faded out.

When a call is finished by a user's operation of the input unit

101 ($t = t_4$), the communication unit 108 transmits a notice of finishing a talk conversation to the control unit 103. When the control unit 103 receives a notice of finishing a talk conversation (Step S901 in Fig. 11), it has the reproduction unit 106 reproduce the music data which was being reproduced when a call arrived (Step S904) according to the resume pattern stored in the resume method storage area 304 of the incoming call processing information storage unit 107 (Steps S902 and S903). Thereby, as shown in ~~a~~ the full line LA1, reproduction of music data which was stopped during a talk conversation (sound volume $v = 0$) is resumed at the volume v_1 which is the sound volume when music data is reproduced after finishing a talk ($t = t_4$) and on receiving a call ($t = t_1$). Note that although, in this case, the processing for controlling the sound volume is not executed when reproduction of music data is started by the resume processing, the fade-in processing may be executed when reproduction of music data is started by the resume processing.

In the above case (2), as shown in ~~a~~ the dotted line LA2, if a call arrives at the time $t = t_1$ while a user is reproducing music data at the sound volume $v = v_1$ (Step S801 in Fig. 10), the control unit 103, as it does in the case (1), reads out the incoming call processing method 309 of the registrant 306 (Step S803) if the caller's phone number matches the phone number 308 of the registrant 306 (Step S802). If they do not match each other, it reads out the incoming call processing method of the incoming call processing method storage area 302 (Step S805). If the incoming call processing method "2" is read out (Step S804), the control unit 103 instructs the reproduction unit 106 to ~~tune~~ turn down the sound volume of the reproducing music data gradually to that for reproducing BGM, instructs the ring tone readout unit 109 to read out the ring tone from the ring tone storage unit 110, and further instructs the reproduction unit 106 to fade in reproduction of the

read-out ring tone (Step S806). Thereby, the reproduction sound of music data is, as shown in ~~a~~ the dotted line LA2, gradually tuned down from the sound volume v1 to a specified volume v2 during the time of $t_1 \leq t \leq t_2$ from the point of receiving a call, and after $t_2 \leq t$,
5 the music data is reproduced as BGM at the constant sound volume v2. On the other hand, the ring tone is faded in while it is being mixed with BGM reproduction sound, as shown in Fig.13B during the time of $t_1 \leq t \leq t_2$, and after reaching a specified sound volume v3 at the time of $t = t_2$, it is reproduced at the sound volume v3. Here,
10 if a user responds to a call ($t = t_3$) (Step S811), the communication unit 108 executes the processing to stop reading out a ring tone by the ring tone readout unit 109 so as to start communication. The BGM reproduction sound of music data is mixed with the communicating voice/sound and reproduced, and outputted from
15 the headphones 3 or the speaker 6, and at the same time transmitted to the user's communicating partner. Thereby, as shown in Fig. 13B, the ring tone is stopped at the time of $t = t_3$. In this case, too, the ring tone may be faded out instead of being stopped.

20 When a call is finished ($t = t_4$), the communication unit 108 transmits a notice of finishing a ~~talk~~ conversation to the control unit 103. The control unit 103 instructs the reproduction unit 106 to ~~tune~~ turn up the BGM reproduction sound volume of music data to the volume on receiving a call if the BGM reproduction is being done
25 when a call is finished. Thereby, as shown in ~~a~~ the dotted line LA2, the BGM reproduction sound volume of music data v2 is returned to the reproduction sound volume of music data on receiving a call v1. Note that, in this case, the BGM reproduction sound volume v2 may be, of course, ~~tune~~ turn up gradually to the sound volume on
30 receiving a call v1.

Note that although BGM reproduction sound of music data is mixed with talking sound and reproduced in this embodiment, BGM

reproduction sound need not always be mixed with communicating voice/sound, and the communicating voice/sound may be outputted from the right (or the left) speaker of the headphones 3 and the BGM reproduction sound of music data from the left (or the right) speaker thereof, for example.

Further, although, in this embodiment, the BGM reproduction sound of music data is also transmitted to the user's communicating partner, the mobile phone with music reproduction function of the present invention is not limited thereto. The BGM reproduction sound of music data along with the communicating voice/sound may be outputted from the headphones 3 or the speaker 6 only without being transmitted to the user's communicating partner. Thereby, there produces an effect that, when the user of the mobile phone with music reproduction function of the present invention has a call, if the receiver is also the user of the mobile phone with music reproduction function, the receiver can also enjoy BGM reproduction of other music data than the music data that the caller is listening to during a ~~talk~~ conversation. Further, a user may set whether or not the BGM reproduction sound is transmitted to his/her communicating partner for each of his/her mobile phone. In addition, a user can set it for each partner.

In the above case (3), a user does not reproduce music data when he/she receives a call. When the control unit 103 receives a notice of receiving a call from the communication unit 108 ($t = t_1$) (Step S1001 in Fig. 12), it instructs the ring tone readout unit 109 to read out the ring tone, and instructs the reproduction unit 106 to ~~fade~~ faded in the reproduction of the read-out ring tone. Thereby, the ring tone is fade in as shown in Fig. 13B during the time of $t_1 \leq t \leq t_2$ from the point of receiving a call, being reproduced at the sound volume v_3 when it reaches a specific volume v_3 at the time of $t = t_2$.

The control unit 103 checks the caller's phone number and the

phone number 308 of each registrant 306 (Step S1002), and if they match each other, it reads out the incoming call processing method 309 of the registrant 306, and if the readout incoming call processing method 309 is "2", it reads out the BGM file name 310 (Step S1003). The control unit 103 waits for a notice of starting communication from the communication unit 108 (Step S1005) since the read-out BGM file name 310 is not "0" (Step S1004), and when it receives a notice of starting communication ($t = t_3$), it instructs the music data readout unit 104 to read out the tune data 203 of the read-out BGM file name 310 from the music data recording medium 105 and further instructs the reproduction unit 106 to reproduce the read-out tune data 203 as BGM (Step S1006). The ring tone is stopped by the process of the communication unit 108.

Thereby, the ring tone is stopped as shown in Fig. 13B when a call starts ($t = t_3$), and on the other hand, as shown in ~~a~~ the dashed line LA3, the BGM reproduction of the tune data 203 specified in the BGM file name 310 is started ($v = v_2$) and mixed with the talking sound. The mixed BGM reproduction sound is outputted from the headphones 3 or the speaker 6 and transmitted to the user's communicating partner. Note that, in this embodiment, the BGM reproduction of the tune data 203 specified in the BGM file name 310 may also be faded in. Also, although the BGM reproduction of the tune data 203 is started in wait for starting communication in the above embodiment, the present invention is not limited to this, and the BGM reproduction or fade-in thereof may be started at the time of receiving a call ($t = t_1$) or an appropriate point of time after receiving a call ($t_1 \leq t \leq t_3$). Further, although the above embodiment describes the BGM reproduction during a ~~talk~~ conversation if the mobile phone 100 with music reproduction function receives a call, the present invention is not limited to this embodiment, and the BGM reproduction during a ~~talk~~ conversation

may be done even if the user of the mobile phone 100 with music reproduction function is a caller. In this case, the BGM reproduction sound can be mixed with the communicating voice/sound so as to be transmitted to the communicating partner or need not be transmitted.

After a call is finished ($t = t_4$), the control unit 103 instructs the music data readout unit 104 to stop reading out the tune data 203 from the music data recording medium 105, and further instructs the reproduction unit 106 to stop reproducing music data.

Thereby, as shown in ~~a~~ the dashed line LA3, the BGM reproduction of music data is stopped ($v = 0$). Note that, even in this case, the BGM reproduction of the tune data 203 may, of course, be faded out when it is stopped.

As described above, the mobile phone 100 with music reproduction function of the present invention fades out the reproducing music on receiving a call and at the same time, fades in the ring tone, thereby producing an effect that a user who is reproducing music can distinguish it from the ring tone more comfortably. In addition, the mobile phone 100 with music reproduction function offers various processes on receiving a call, during ~~a talk~~ conversation and after finishing ~~a talk~~ conversation, respectively, thereby producing an effect that it can meet users' diversified needs which may arise because it has both functions of a music reproduction player and a mobile phone.

Fig. 14A is a timing chart that shows the sound volume transition of the music data reproduction sound of the mobile phone 100 with music reproduction function if a user does not respond to a call within the time specified Δt . Fig. 14B is a timing chart that shows the volume transition of the ring tone of the mobile phone 100 with music reproduction function if a user does not respond to a call within the time specified Δt . In Fig. 14A, the sound volume transition as shown in a full (solid) line la1 is same as the sound

volume transition (1) as shown in Fig. 13A. The sound volume transition as shown in a dotted line 1a2 is same as the sound volume transition (2) as shown in Fig. 13A. The sound volume transition as shown in a dashed line 1a3 is same as the sound volume transition (3) as shown in Fig. 13A. Therefore, since the sound volume transitions on receiving a call ($t_1 \leq t \leq t_2$) as shown in Fig. 14A and Fig. 14B are same as those on receiving a call ($t_1 \leq t \leq t_2$) as shown in Fig. 13A and Fig. 13B, explanation thereof will be omitted. Note that $t_5 = t_1 + \Delta t$ here.

In the case (1), although only the ring tone is being reproduced at a constant sound volume ($v = v_3$) ($t_2 \leq t < t_5$), a user does not respond to a call even after the specified time Δt has passed ($t = t_5$) since the call arrived (Step S811 in Fig. 11). In this case, the control unit 103 instructs the reproduction unit 106 to fade out the ring tone, reads out the file name of the music data which was being reproduced on receiving a call (the resume file name 311), instructs the music data readout unit 104 to read out the music data of the read-out file name from the beginning thereof, and instructs the reproduction unit 106 to fade in and mix the read-out music data with the ring tone so as to start reproduction thereof. After the fade-out of the ring tone is completed ($t = t_6$), the control unit 103 instructs the ring tone readout unit 109 to stop reading out the ring tone, and instructs the reproduction unit 106 to stop reproduction of the ring tone (Step S812). On the other hand, when the reproduction sound of the music data which is being faded in reaches the sound volume on receiving a call ($v = v_1$) ($t = t_6$), the control unit 103 instructs the reproduction unit 106 to reproduce the music data at the ~~said~~ sound volume v_1 .

Thereby, at the same time when the ring tone is faded out as shown in Fig. 14B ($t_5 \leq t \leq t_6$, $v_3 \geq v \geq 0$), the reproduction of the music data which was stopped on receiving a call is faded in again as shown in ~~a~~ the full line 1a1 in Fig. 14A ($t_5 \leq t \leq t_6$, $0 \leq v \leq v_1$),

returning to the reproduction condition on receiving a call. Note that although the reproduction of the music data which was stopped on receiving a call is resumed from the beginning thereof according to the present embodiment, the present invention is not limited to this embodiment, and it may be resumed at the resume position based on other resume patterns, or may be resumed at the resume position based on the resume patterns stored in the resume method storage area 304.

In the case (2), if a user does not respond to a call even after the specified time Δt has passed from the point of receiving a call ($t = t_5$) while the ring tone at a certain volume ($v = v_3$) is being reproduced ~~with~~ and mixed with the BGM reproduction sound ($v = v_2$) ($t_2 \leq t < t_5$), the control unit 103 instructs the reproduction unit 106 to fade out the ring tone, and then instructs it to ~~tune~~ turn up the BGM reproduction sound volume of the music data v_2 to the volume v_1 on receiving a call. Next, after the fade-out of the ring tone is finished ($t = t_6$), the control unit 103 instructs the ring tone readout unit 109 to stop reading out the ring tone, and instructs the reproduction unit 106 to stop reproducing the ring tone.

Thereby, as shown in Fig. 14B, at the same time when the ring tone is faded out as mentioned above ($t_5 \leq t \leq t_6$, $v_3 \geq v \geq 0$), the sound volume of the music data which was being reproduced as BGM v_2 is ~~tuned~~ turned up gradually to the sound volume v_1 on receiving a call ($t_5 \leq t \leq t_6$, $v_2 \leq v \leq v_1$), as shown in ~~a~~ the dotted line 1a2 in Fig. 14A, returning to the reproduction condition at the point of receiving a call.

In the case (3), the control unit 103 executes the processing corresponding to Step S1001 through Step S1005 in Fig. 12 after the communication unit 108 gives a notice of starting a ~~talk~~ conversation. However, since the reproduction condition returns to that at the point of receiving a call before the communication unit 108 gives a notice of receiving a call, the BGM reproduction of music

data is not done accordingly, and only the ring tone is reproduced as shown in Fig. 14B.

As described above, according to the present embodiment, the mobile phone 100 with music reproduction function once
5 executes the incoming call processing based on the incoming call processing method 309 or in the incoming call processing method storage area 302 when it receives a call. Since ~~it~~ the mobile phone 100 automatically returns the reproduction of music data to the condition before receiving a call if a user does not respond to a call
10 within a specified time Δt , the user may just ~~leave~~ not respond to a call ~~not responded~~ if he/she has no will to respond to it or need not respond it by return as long as he/she can check receipt of a call and the caller's phone number, thereby producing an effect that a user need not bother to operate the input unit 101 to return to the
15 original condition and therefore, it is very convenient for him/her.

Note that above-mentioned embodiment is just an explanatory example of a system which promises the best effect under the present situation. The present invention may be embodied in other specific forms without departing from the spirit
20 thereof. Specifically, the present invention may be embodied in the following forms.

Although the music data recording medium 105 is described as a portable semiconductor memory according to the present embodiment, the present invention is not limited to this, and it can
25 be replaced with a small-sized hard disk other than a portable semiconductor memory, a built-in memory of the mobile phone 100 with music reproduction function or the like.

Although ~~3~~ three types of resume patterns are explained according to the present embodiment, the present invention is not,
30 of course, limited to this. Also, although the resume pattern selected by a user's input is stored in the resume method storage area 304 according to the present embodiment, the present

invention is not limited to this, and the mobile phone 100 with music reproduction function may select the resume pattern at random.

Note that although it is assumed in the present embodiment that the music data obtained via electronic music distribution is recorded in the music data recording medium 105 so as to be reproduced, the present invention is not limited to this. For example, ambient sound which a user himself/herself recorded or obtained in another way, such as conversation in conference, babbling sound of a stream, or noise of busy train station, is converted into a file format and recorded in the music data recording medium 105 along with the above-mentioned music data, and the file thereof may be reproduced as BGM.

Although the sound volume is ~~tuned~~ turned down to a specified volume when the music data is reproduced as BGM in the above-mentioned embodiment, the present invention is not limited to this, and even in the BGM reproduction thereof, the music data can be just mixed with the communicating voice/sound and reproduced at the same volume as it was before receiving a call. In this case, a user can control the BGM reproduction sound volume by operating the volume control buttons on the music reproduction control key unit 9 or the music reproduction control key unit 13. Or, a user can set the BGM reproduction sound volume beforehand.

Note that although the ring tone is always reproduced in the above-mentioned embodiment on the assumption that a user responds to a call when a call arrives, the present invention is not limited to this, and the ring tone need not be reproduced depending on a caller. In this case, a user registers the phone number of the caller whom the user will not respond to in the phone number 308 of the phone book storage area 301, stores "0", for example, in the incoming call processing method 309 for the registrant. The control unit 103 examines the phone book storage area 301 when a call arrives, and if the incoming call processing method 309 is "0",

completes the incoming processing without executing any processing. Thereby, since the sound volume of the music data is not ~~tuned~~ turned down even if the music data is being reproduced on receiving a call without reproduction of the ring tone, a user, if he/she knows the caller's phone number, can register it and store "0" in the incoming call processing method 309, thereby producing an effect that a user can enjoy music without being bothered by a silent call, nuisance call or a call from an unwelcome person.

10 **INDUSTRIAL APPLICABILITY**

Although a mobile phone is described in the form of the present embodiment, the present invention is applicable to a mobile phone with a music reproduction function, a PDA (personal digital assistant) with a music reproduction function or a phone function, and a portable communication device with a music reproduction function and a phone function.

ABSTRACT

A mobile phone ~~100~~ with music reproduction function ~~comprising~~
5 has a reproduction unit ~~106~~ that reproduces music data and a ring
tone which are recorded in a music data recording medium ~~105~~ ~~and~~
~~a ring tone, and~~ a communication unit 108 that detects an incoming
call from outside. ~~and~~ The mobile phone 100 has a control unit ~~103~~
that instructs the reproduction unit ~~106~~ to perform a fade-out
process of reproducing the music data and to perform a fade-in
10 process of outputting ~~a~~ the ring tone when the communication unit
~~108~~ detects an incoming call while the reproduction unit ~~106~~ is
reproducing music data.

SPECIFICATION

TITLE OF THE INVENTION

MOBILE PHONE WITH MUSIC REPRODUCTION FUNCTION

5

CLAIMS

1. A mobile phone with music reproduction function comprising:
a communication unit operable to detect an incoming call
from outside;
10 a reproduction unit operable to reproduce music data and a
ring tone; and
a control unit operable to instruct the reproduction unit to
stop reproduction of music data which is being reproduced after
performing fade-out processing of the music data, and to reproduce
15 a ring tone during performing fade-in processing of the ring tone,
when the control unit receives an incoming call notice from the
communication unit during the reproduction of the music data.
2. The mobile phone according to Claim 1,
20 wherein the control unit further performs predetermined
incoming call processing when the control unit receives an incoming
call notice from the communication unit during reproduction of
music data, and
instructs the reproduction unit to stop reproduction of a ring
25 tone which is being reproduced after performing fade-out
processing of the ring tone, and to reproduce music data during
performing fade-in processing of the music data, when the incoming
call is not responded to for a predetermined period of time.
- 30 3. A mobile phone with music reproduction function comprising:
a communication unit operable to detect an incoming call
from outside; and

a reproduction unit operable to reproduce music data,
wherein reproduction of music data is not stopped when a call
arrives during the reproduction of the music data, and is
continuously reproduced as background music during a talk.

5

4. The mobile phone according to Claim 3 further comprising:
a storage unit operable to store a phone book list per caller
including at least a phone number of a caller and incoming call
processing information which describes whether reproduction of
10 music data is stopped or not when a call arrives during the
reproduction of the music data; and

a control unit operable to compare the phone number of the
caller received by the communication unit with the phone number
stored in the storage unit, and when both phone numbers
15 correspond with each other as a result of the comparison, to control
the processing of stopping or not stopping the reproduction of the
music data based on the incoming call processing information stored
in the storage unit.

20 5. The mobile phone according to Claim 3 further comprising:
a storage unit operable to store a phone book list per caller
including at least a phone number of a caller and music data which
should be reproduced as background music when a call arrives
during no reproduction of music data; and

25 a control unit operable to compare the phone number of the
caller received by the communication unit with the phone number
stored in the storage unit, and when both phone numbers
correspond with each other as a result of the comparison, instructs
the reproduction unit to reproduce a predetermined music data as
30 background music during a talk based on the incoming call
processing information stored in the storage unit.

6. A mobile phone with music reproduction function comprising:
a communication unit operable to detect an incoming call
from outside;

a reproduction unit operable to reproduce music data;

5 a holding unit operable to hold one or more reproduction
resume methods; and

a control unit operable to determine a readout position of
music data after a talk finishes based on a predetermined
reproduction resume method held in the holding unit, and to instruct
10 the reproduction unit to reproduce the music data from the
determined readout position.

7. The mobile phone according to Claim 6,

wherein the music data stores resume position information
15 concerning selectable reproduction resume points, and

the reproduction resume method is one of the following
reproduction resume points stored in the resume position
information: the beginning of music data; the point run back for a
predetermined time from the point at which the music data was
20 being reproduced when a call arrived, and the point just before the
point at which the music data was being reproduced when the call
arrived.

DETAILED DESCRIPTION OF THE INVENTION

TECHNICAL FIELD

25 The present invention relates to a mobile phone with music
reproduction function, and especially relates to a mobile phone that
provides various operations at the time of a call arrival during
30 reproduction of music data.

PRIOR ART

A memory has been remarkably miniaturized and had larger capacity in recent years. In addition, thanks to advance of audio compression techniques, new compression methods such as MP3 (MPEG1 Audio Layer 3) have been suggested, wherein the quality of original sound in LPCM (Linear Pulse Code Modulation) is not so deteriorated as to be unfitted for comfortable listening even if it is compressed into one tenth of the original one. As these techniques have developed, it has become possible, for example, to record music data for one album on a stamp-sized semiconductor memory.

On the other hand, from a viewpoint of music distribution, in addition to the conventional distribution via package media such as cassette tapes and CDs, there are indications that the form of directly downloading music data via Internet or the like (hereinafter referred to as "electronic music distribution") has been widely used.

In the electronic music distribution, as mentioned above, a form of downloading music data via Internet using a personal computer (PC) is popular. However, since a PC costs lots of initial investment, other distribution channels than PC-Internet have been considered, and among them, a form of downloading music data by using a mobile phone has attracted much attention. Although a mobile phone has now problems of slow communication speed and high communication cost, it is expected to be one of the leading distribution channels if these problems are overcome by future improvement of communication technology. This is because mobile phones are very widely used and they need not so much cost of equipments required for electronic music distribution as PCs.

Here, if it is considered that music data is downloaded by a mobile phone for listening to music, as shown in Fig. 11, it may happen that after recording downloaded music data onto the portable recording medium 1103, the recording medium 1103 is removed from a mobile phone 1101 and then inserted again into a music reproduction player 1102 for reproduction thereof. However,

since carrying about both a mobile phone and a music reproduction device on the way to office and/or school means occupying space such as a bag with them, a mobile phone with music reproduction function, that is a composite machine of a mobile phone and a music reproduction device was invented and disclosed in Japanese Laid-Open Patent Application H09-321844 and others. However, as this kind of composite machine is just based on a phone, processing which is not required for an ordinary music reproduction device is needed to be considered if a call arrives during music reproduction.

These problems will be described in detail.

For example, assuming that a call is received during listening to music by using the composite machine of the mobile phone and the music reproduction device, it will be found that the composite machine has the following problems:

(1) Processing on receiving a call

An ordinary mobile phone notifies a user of an incoming call mainly by sound (a ring tone). However, the composite machine must notify a user of a ring tone without fault even while the user is listening to music through headphones. Particularly if a melody tone is set to announce an incoming call, the music which the user is listening to must be clearly distinguished from the melody tone which is reproduced when the call arrives. It can be said that, in order to notify the user of the incoming call without fault, it is desirable to turn down the volume of the reproducing music, mute it, or ring a ring tone after the reproducing music is temporarily stopped.

On the other hand, the incoming call does not always need to be notified. Various patterns of processing are requested according to the setting of the mobile phone, such as continuing the reproduction of the music without stopping it even when the call arrives, or resuming the reproduction of the music after a predetermined time of seconds have passed when the user does not

talk although the ring tone rings. However, there is no such mobile phone.

(2) Processing During a Talk

Although it is generally desirable to stop reproducing music data during a talk, the music reproduction need not always be stopped if a communicating partner over a phone is a close person like a family member. According to the current phone system, the receiver of the call can identify a phone number of a caller if he/she makes the setting of notifying the phone number. Using this system, if the user makes the setting of whether the reproduction of the music data is stopped or not corresponding to the caller's phone number, it becomes possible to determine per caller whether the music is reproduced as BGM or not during a talk.

(3) Reproduction Resume

When the composite machine temporarily stops the music reproduction, it performs an operation of resuming the music reproduction after the talk finishes. However, the problem is that, unlike the music player in use for music reproduction only, in the composite machine, the music reproduction is interrupted by the incoming call regardless of the user's will, that is, it is forced to be interrupted. Therefore, it can be easily imagined that users may make requests such as not only resuming the music reproduction at the point at which the music was being reproduced when the call arrived, but also resuming the music reproduction at the point run back for a predetermined period from the point of receiving the call, or resuming the music reproduction from the beginning of the music.

PROBLEMS THE INVENTION IS TO SOLVE

As mentioned above, the problems of the composite machine of the mobile phone and the music reproduction device that may occur when a call arrives during music reproduction have not yet

sufficiently considered. It is accordingly an object of the present invention, in the light of the above-mentioned conventional problems, to provide a more user-friendly composite machine of a mobile phone and a music reproduction device (hereinafter referred to as "a mobile phone with music reproduction function") by providing various manners of the music reproduction processing on receiving a call and the reproduction resume processing after a talk finishes.

MEANS TO SOLVE PROBLEMS

The above-mentioned problems may be solved by a mobile phone with music reproduction function according to Claim 1 of the present invention comprising a communication unit operable to detect an incoming call from outside, a reproduction unit operable to reproduce music data and a ring tone, and a control unit operable to instruct the reproduction unit to stop reproduction of music data which is being reproduced after performing fade-out processing of the music data, and to reproduce a ring tone during performing fade-in processing of the ring tone, when the control unit receives an incoming call notice from the communication unit during the reproduction of the music data.

Also, the mobile phone according to Claim 2 of the present invention is, in addition to the mobile phone according to Claim 1, the mobile phone with music reproduction function wherein the control unit further performs predetermined incoming call processing when it receives the incoming call notice from the communication unit during the reproduction of the music data, and instructs the reproduction unit to stop the reproduction of the ring tone which is being reproduced after performing the fade-out processing of the ring tone, and to reproduce the music data during performing the fade-in processing of the music data, when the control unit does not respond to the incoming call for a

predetermined period of time.

Also, the mobile phone according to Claim 3 of the present invention is a mobile phone with music reproduction function comprising a communication unit operable to detect an incoming call
5 from outside, and a reproduction unit operable to reproduce music data, wherein reproduction of music data is not stopped when a call arrives during the reproduction of the music data, and is continuously reproduced as background music during a talk.

Also, the mobile phone according to Claim 4 of the present
10 invention is, in addition to the mobile phone according to Claim 3, the mobile phone with music reproduction function comprising a storage unit operable to store a phone book list per caller including at least a phone number of a caller, and incoming call processing information which describes whether reproduction of music data is
15 stopped or not when a call arrives during the reproduction of the music data, and a control unit operable to compare the phone number of the caller received by the communication unit and the phone number stored by the storage unit, and when both phone numbers correspond with each other as a result of the comparison,
20 to control the processing of stopping or not stopping the reproduction of the music data based on the incoming call processing information stored in the storage unit.

Also, the mobile phone according to Claim 5 of the present invention is, in addition to the mobile phone according to Claim 3,
25 the mobile phone with music reproduction function comprising a storage unit operable to store a phone book list per caller including at least a phone number of a caller, and music data which should be reproduced as background music when a call arrives during no reproduction of music data, and a control unit operable to compare
30 the phone number of the caller received by the communication unit with the phone number stored by the storage unit, and when both phone numbers correspond with each other as a result of the

comparison, instructs the reproduction unit to reproduce a predetermined music data as a background music during a talk based on the incoming call processing information stored in the storage unit.

5 Also, the mobile phone according to Claim 6 of the present invention is a mobile phone with music reproduction function comprising a communication unit operable to detect an incoming call from outside, a reproduction unit operable to reproduce music data, a holding unit operable to hold one or more reproduction resume
10 methods, and a control unit operable to determine a readout position of music data after a talk finishes based on a predetermined reproduction resume method held in the saving unit, and to instruct the reproduction unit to reproduce the music data from the determined readout position.

15 The mobile phone according to Claim 7 of the present invention is, in addition to the mobile phone according to Claim 6, the mobile phone with music reproduction function, wherein the music data stores the resume position information concerning selectable reproduction resume points, and the reproduction
20 resume method is one of the following reproduction resume points stored in the resume position information: the beginning of the music data; the point run back for a predetermined time from the point at which the music data was being reproduced when the call arrived, and the point just before the point at which the music data
25 was being reproduced when the call arrived.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The following is a detailed explanation of a structure of a mobile phone with music reproduction function according to one
30 embodiment of the present invention with reference to figures. In the present embodiment, the explanation will be given on the assumption that the data subject to reproduction is limited to music

data. Note that, however, the present invention is not limited to this embodiment, and may, of course, be embodied in combination of image data, text data and music data.

Fig. 1 is a diagram that shows a structure of a mobile phone 100 with music reproduction function of the present invention. The mobile phone 100 with music reproduction function of the present invention is typically a composite machine of a mobile phone and an audio reproduction player, and can be used as a personal headset stereo when it is not used as a phone. The mobile phone 100 with music reproduction function comprises an input unit 101, a display unit 102, a control unit 103, a music data readout unit 104, a music data recording medium 105, a reproduction unit 106, an incoming call processing information storage unit 107, a communication unit 108, a ring tone readout unit 109, and a ring tone storage unit 110. These components will be explained as follows.

The input unit 101 is a means for accepting user's instructions by keys or buttons. The user's instructions include an input of a phone number for making a call, and an instruction of reproducing, stopping, fast-forwarding and rewinding music, for example.

The display unit 102 is a liquid crystal display unit for displaying a phone number, a music number for playing and others.

The control unit 103, which is typically a CPU equipped with a ROM/RAM, controls each unit of the mobile phone 100 with music reproduction function based on a program stored in the ROM/RAM. This means, for example, that the control unit 103 interprets a user's instruction of inputting a phone number via the input unit 101, performs control of instructing the communication unit 108 to make a call, and instructs the display unit 102 to display the phone number inputted by the user. Also, if the user gives instructions to reproduce music via the input unit 101, the control unit 103 instructs the after-mentioned music data readout unit 104 to read out music data.

Further, when a call arrives, the control unit 103 instructs the music data readout unit 104 to stop reading out the music data, instructs the reproduction unit 106 to start fading out the music which is being reproduced, and instructs the ring tone readout unit
5 109 to read out the ring tone stored in the ring tone storage unit 110.

Further, when a talk finishes, the control unit 103 reads out the resume position information stored in the incoming call processing information storage unit 107, and instructs the music
10 data readout unit 104 to read out the music data based on the read-out resume position information.

The music data readout unit 104 is a means for reading out the music data or the like recorded in the after-mentioned music data recording medium 105 based on the instruction by the control
15 unit 103 to read out the music data.

The music data recording medium 105 is typically a small-sized portable recording medium such as a semiconductor memory, and the compressed music data, for example, is recorded thereon. Note that the music data recording medium 105 need not
20 always be removable from the mobile phone 100 with music reproduction function of the present invention, and may be built in the mobile phone 100 with music reproduction function.

Fig. 2 is a diagram that shows data structure of digital data which is recorded in a music data recording medium 105 according to the embodiment of the present invention. The music data
25 recording medium 105 is typically a read/write semiconductor memory. The music data recording medium 105 has a sector structure. Each sector stores digital data of 512 bytes according to the present embodiment. The music data recording medium 105
30 stores file system information for managing multiple sectors as a file in a predetermined sector group. The file system applied for the music data recording medium 105 is based on the file system

prescribed under ISO9293.

According to the present invention, the digital data is stored in the music data recording medium 105 in a file format. Fig. 2 shows digital data stored in a file format and a data structure of reproduction path information which defines reproduction order of the digital data.

A song data storage area 201 is an area in which, song data 203 recorded in an MPEG2-AAC (Advanced Audio Coding) format, for example, is stored. Note that, according to this embodiment, $0 \leq N \leq 999$ song data, that is, a maximum of 999 song data can be stored in the song data storage area 201.

On the other hand, a reproduction path management area 202 is information that defines reproduction order of the digital data recorded in the music data recording medium 105, and is comprised of a number of melodies 204 indicating the number of the digital data recorded in the music data recording medium 105 and reproduction control information 205 of each digital data recorded in the music data recording medium 105.

The number of songs 204 is the information indicating the number of pieces of the digital data recorded in the music data recording medium 105, and $0 \leq N \leq 999$, that is, a maximum of 999 data can be recorded according to the present embodiment, as described above in the explanation of the song data 203.

The reproduction control information 205 is comprised of a file name 206 that is an area for storing a file name, a number of access points 207 for storing a number of address positions which can be selected for possible reproduction resume points when music reproduction is resumed as described later, and an access point 208 that is an address position which can be selected for a reproduction resume point when music reproduction is resumed. Note that, according to this embodiment, the number of access points 207 is $0 \leq M \leq 99$, that is, 99 at maximum.

By the way, the music data recording medium 105 is equipped with a so-called FAT (File Allocation Table) file system prescribed under ISO9293 as described before, and can identify the said file based on the file name described in the file name 206 so as to specify the recording start address and recording end address of the song data 203 based on the information of the FAT table.

Further, in reproducing music, the song data 203 is reproduced in the order described in the reproduction control information 205. For example, if the song data #1 is described in the reproduction control information #1, the song data #3 in the reproduction control information #2, and the song data #2 in the reproduction control information #3, respectively, the song data is reproduced in the order of the data #1, #3 and #2.

As mentioned above, it is found that the digital data and the reproduction order thereof can be defined according to the structure of the digital data as shown in Fig. 2.

Next, the components of the mobile phone 100 with music reproduction function will be explained with reference to Fig. 1 again.

The reproduction unit 106 is a means for decoding, D/A converting and reproducing the music data which was read out by the music data readout unit 104. Also, it has a sound volume control function. The decoded music can be listened to over headphones or the like.

The incoming call processing information storage unit 107 is typically an EEPROM (Electrically Erasable Programmable Read-Only Memory), and a memory that stores the position information of the music data which is being reproduced when the control unit 103 gives instructions to stop the music data. Also, the control unit 103 refers to the position information when it resumes reproduction of music data, identifies appropriate music data and a detailed readout position thereof, and instructs the music data readout unit 104 to

read out the music data.

Also, the incoming call processing information storage unit 107 stores a phone book registered by a user of the mobile phone 100 with music reproduction function. Or it stores a value set per communicating partner who is registered based on the processing method when a call arrives from him/her. The structure of the incoming call processing information storage unit 107 will be explained in detail as follows.

Fig. 3 is a diagram that shows a data structure of an incoming call processing information storage unit 107. As shown in Fig. 3, the incoming call processing information storage unit 107 is comprised of a phone book storage area 301, an incoming call processing method storage area 302, a resume information storage area 303 and a resume method storage area 304. Each of these areas will be explained as follows.

The phone book storage area 301 is an area for storing the information of communicating partners' phone numbers and names registered by a user of the mobile phone 100 with music reproduction function of the present. The phone book storage area 301 is further comprised of a number of registrants 305 and a registrant 306, as shown in Fig. 3.

The number of registrants 305 is the information indicating how many registrants' data are registered in the phone book storage area 301, and $0 \leq L \leq 99$, that is, a maximum of 99 registrants can be registered.

The registrant 306 is further comprised of a registrant name 307, a phone number 308, an incoming call processing method 309 and BGM file name 310. These will be explained as follows.

The registrant name 307 stores a name set by a user when he/she registers a communicating partner in the phone book storage area 301, as mentioned above. The phone number 308 describes a phone number set by a user when he/she registers a communicating

partner in the phone book storage area 301. The incoming call processing method 309 indicates a processing method per registrant (communicating partner over a phone) when a call arrives from him/her, and it writes "1" if music reproduction is stopped and a ring tone is reproduced when a call arrives, for example. It writes "2" if music is reproduced as BGM during a talk without stopping reproduction thereof when a call arrives. In the BGM file name 310, the file name of the music data that is to be reproduced as BGM is described when a call arrives from a specific communicating partner while the music data is not being reproduced. If the file name of the music data that is to be reproduced as BGM is not specified, "0" is written.

Note that, according to the present embodiment, when the incoming call processing method 309 is "2" and a call arrives during reproduction of music data, the reproducing music data is continued to be reproduced as BGM without stopping it. Also, when the incoming call processing method 309 is "2" and a call arrives while music data is not being reproduced, the music data having the file name written in the BGM file name 310 is reproduced as BGM. The present invention is not, of course, limited to this embodiment, but when a call arrives during reproduction of music data and the incoming call processing method 309 is "2", for example, the reproduction of the music data can be stopped once so as to reproduce the music data having the file name written in the BGM file name 310 as BGM.

Next, the incoming call processing method storage area 302 is an area for storing a processing method on receiving a call. The processing method on receiving a call is as follows: If reproduction of music data is stopped and a ring tone is reproduced when a call arrives during the reproduction of the music data, "1" is written. If reproduction of music data is not stopped when a call arrives and the music data is reproduced as BGM during a talk, "2" is written.

Note that these values are same as those written in the incoming call processing method 309 in the phone book storage area 301. The incoming call processing method for a specific caller who is registered in the phone book storage area 301 can be set in the incoming call processing method 309, while the incoming call processing method storage area 302 is an area for storing the processing method on receiving a call for a caller who is not registered in the phone book storage area 301.

The resume information storage area 303 is comprised of the file name 311 and the incoming call reproduction position information 312, as shown in Fig. 3.

The file name 311 is an area for storing a file name which is being reproduced if music data is being reproduced when a call arrives. On the other hand, the incoming call reproduction position information 312 is an area for storing address information indicating reproduction position of music data if the music data is being reproduced when a call arrives.

Fig. 4 is a diagram that shows one example of information which is stored in the incoming call processing method storage area 302. As shown in Fig. 4, the information is comprised of a resume file name 401 and incoming call reproduction position information 402. In the resume file name 401, the file name "Song01.aac" of the music data is written which is being reproduced when a call arrives, that is, when the control unit 103 gives instructions to stop reproducing the music data. On the other hand, in the incoming call reproduction position information 402, the reproduction position of the file, which is being reproduced when a call arrives, that is, when the control unit 103 gives instructions to stop reproducing the music data, is written as a number of bytes from the beginning of the file, "1234", for example. It is possible to specify the file of the music data which is being reproduced when a call arrives and the reproduction position of the file according to these information.

The resume method storage area 304 is an area for storing a resume method. The resume methods will be explained in detail with reference to Figs. 5, 6 and 7. The resume method storage area 304 stores one of the values indicating the resume methods, that is, resuming reproduction from the beginning of the song, resuming reproduction at the position rewound for a predetermined time of seconds, or others.

Next, the components of the mobile phone 100 with music reproduction function will be explained with reference to Fig. 1 again.

A communication unit 108 includes an antenna, a wireless transmission/reception unit and a communication interface which communicate with base stations by wireless. Also, it notifies the control unit 103 of an arrival of a call when the call arrives.

A ring tone readout unit 109 reads out a ring tone from the after-mentioned ring tone storage unit 110, in response to the instructions from the control unit 103 of reading out the ring tone.

The ring tone storage unit 110 is a recording medium in which a ring tone for a phone is stored. The ring tone which can be recorded therein is not limited to one, in other words, more than one ring tones may be recorded. In this case, the ring tone which is to be read out may be preset, or selected at random.

The processing on resuming by the mobile phone 100 with music reproduction function as structured as above will be explained in more detail with reference to Figs. 5, 6 and 7.

Fig. 5 is a diagram that shows three examples of resume methods. In Fig. 5, assume that the song data 203 is being reproduced from a song beginning 501, an arrival of a call is detected at the position shown as an incoming call point 503, and the control unit 103 instructs the reproduction unit 106 to stop reproducing music data. Here, according to the resume method as shown in the resume pattern ①, reproduction is resumed at an

address stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107. Next, according to the resume method as shown in the resume pattern ②, reproduction is resumed at a resume position 5 502 which is run back for a specified value from an address stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107. Here, running back for a specified value means resuming reproduction at the point run back for 5 seconds, for example, from the point of reproduction on receiving a call. Note that, in order to run back for a specified value, it is necessary to store an address from the beginning of a file per second, for example, in a RAM on reproducing and calculate an appropriate address at which reproduction is resumed based thereon.

15 Finally, according to the resume pattern ③, regardless of an address value stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107, reproduction is resumed from the song beginning 501. Fig. 6 describes specific figures indicating the resume positions according to these three types of resume methods.

20 As shown in Fig. 6, a resume pattern 601 shows three types of resume patterns. Incoming call reproduction position information 602 shows address information from the beginning of the file of the song data 203 which is being reproduced when a call arrives. 25 Resume position information 603 indicates at which position of the song data 203 the reproduction thereof is resumed among three types of resume methods, respectively. Further, assume that the address which is stored in the incoming call reproduction position information 312 in the incoming call processing information storage unit 107 is "1234". In this case, according to the resume pattern ①, 30 the address as resume position information is also "1234", since the reproduction is resumed at the point of receiving a call. Next,

according to the resume pattern ②, the resume position is run back for a specified value from the point of receiving a call. "765" indicates the address value which is run back for the said specified value from "1234". Lastly, according to the resume pattern ③, the address as resume position information is "0" since the reproduction is resumed from the song beginning 501.

Next, Fig. 7, which is a variation example of the resume pattern ②, is a diagram that shows one example of methods of specifying a resume position by using the access point 208 in the music data recording medium 105. For example, points which seem to be preferable for a user to resume reproduction such as the beginning of the first chorus, the beginning of the second chorus or the beginning of each passage are stored beforehand in the access point 208. According to the present embodiment, four access points, a first access point 704, a second access point 705, a third access point 706 and a fourth access point 707 are registered therein. In Fig. 7, assume that the song data 203 is reproduced from a song beginning 701, an arrival of a call is detected at the position shown as a first incoming call point 702, and the control unit 103 instructs the reproduction unit 106 to stop reproducing music data. It is indicated that the reproduction is resumed at the point run back to the first access point 704 which is an access point just before the first incoming call point 702. On the other hand, assume that the song data 203 is reproduced from the song beginning 701, an arrival of a call is detected at the position shown as a second incoming call point 703, and the control unit 103 instructs the reproduction unit 106 to stop reproducing the song data 203. It is indicated that the reproduction is resumed at the point run back to the third access point 706 which is an access point just before the second incoming call point 703. Note that the reproduction may be resumed from the song beginning 701 when there is no access point.

As described before, a user can determine the resume

position based on the resume method corresponding to the resume pattern. As a result, a variety of resume methods can be realized flexibly at a user's request.

5 Next, the operations of the mobile phone 100 with music reproduction function as structured above will be explained on the processing on receiving a call during reproduction of music by using flowcharts of Fig. 8.

10 In Step S801, the mobile phone 100 with music reproduction function waits for an arrival of call while it is reproducing music data. When a call arrives, the processing goes on from Step S801 to Step S802. In Step S802, it is determined whether or not a caller has been already registered in the phone book storage area 301. If the caller has been already registered as a result of determination, the incoming call processing method 309 is read out in Step S803, and
15 then the processing goes on to Step S804. On the other hand, if the caller has not registered in the phone book storage area 301 as a result of determination of Step S802, the incoming call processing method stored in the incoming call processing method storage area 302 is read out in Step S805, and then the processing goes on to
20 Step S804.

25 In Step S804, it is determined, based on the incoming call processing method 309 or the incoming call processing method stored in the incoming call processing method storage area 302, whether reproduction of music data should be stopped or continued as BGM. If it is determined to stop the reproduction of the music data, the processing goes on to Step 807, and if it is determined to continue the reproduction of the music data as BGM, the processing goes on to Step S810.

30 In Step S807, the reproducing music data is faded out and muted as well. Further, in Step S808, the reproduction of the music data is stopped, and then in Step S809, the information of the stopping point, that is, the resume position information is recorded.

Further, in Step S810, a predetermined ring tone is reproduced and faded in at the same time.

In Step S811, it is determined whether or not a user responded to a call within a predetermined time, and when the user responded to the call within the predetermined time, the processing finishes. On the other hand, when the user did not respond to the call within the predetermined time, the reproduction of the ring tone is stopped and the reproduction of the music data is resumed if the reproduction thereof is stopped, and the processing finishes.

On the other hand, the processing on resuming reproduction of music will be explained by using a flowchart in Fig. 9.

The mobile phone 100 with music reproduction function waits for a notice of finishing a talk in Step S901. When there is a notice of finishing a talk, the resume method is determined in Step S902.

Here, the resume method should be based on that stored in the resume method storage area 304. Next, in Step S903, the music data which was determined to be resumed and reproduced in Step S902 is specified, and the reproduction position of the music data is also specified. In Step S904, the music is reproduced from the position specified in Step S903.

Fig. 10 is a flowchart that shows operations of the mobile phone 100 with music reproduction function while music data is not being reproduced.

The mobile phone 100 with music reproduction function waits for a notice of receiving a call from the control unit 103 in Step S1001. When there is a notice of receiving a call, the processing goes on from Step S1001 to Step S1002.

In Step S1002, it is determined whether or not a caller is registered in the phone book storage area 301. When it is found, as a result of the determination, that the caller is registered, the BGM file name 310 is read out in Step S1003, and then the processing goes on to Step S1004. When it is found, as the result of the

determination in Step S1002, that the caller is not registered in the phone book storage area 301, the processing finishes.

In Step S1004, it is determined whether a file name is specified or not based on the read-out BGM file name 310. When
5 the file name is specified, the processing goes on to Step S1005. On the other hand, when the file name is not specified, the processing finishes.

In Step S1005, a notice of starting a talk from the communication unit 108 is waited for. When the notice of starting a
10 talk is received, the processing goes on to Step S1006. In Step S1006, the reproduction of the music data specified by the BGM file name 310 is started, and the processing finishes.

The explanation of the operations of the mobile phone 100 with music reproduction function according to the present invention
15 is completed.

Note that above-mentioned embodiment is just an explanatory example of a system in which the best effect under the present situation is expected. The present invention may be embodied in other specific manners without departing from the
20 spirit thereof. Specifically, the present invention may be embodied in the following manners:

Although the music data recording medium 105 is described as a portable semiconductor memory according to the present embodiment, the present invention is not limited to this, and it can
25 be replaced with a small-sized hard disk other than a portable semiconductor memory, a built-in memory of the mobile phone 100 with music reproduction function or the like.

Although three types of resume patterns are explained according to the present embodiment, the present invention is not,
30 of course, limited to this. Also, although the resume pattern is stored in the resume method storage area 304 according to the present embodiment, the present invention is not limited to this,

and the mobile phone 100 with music reproduction function may select the resume pattern at random.

EFFECTS OF THE INVENTION

5 As mentioned above, the mobile phone 100 with music reproduction function according to the present invention, which can perform various types of processing when a call arrives or a talk finishes, is of great advantage for applicability.

BRIEF DESCRIPTION OF THE DRAWINGS

ABSTRACT OF THE DISCLOSURE

ABSTRACT

5 OBJECT

To provide a mobile phone that prescribes various types of processing on receiving a call during reproduction of music and processing on resuming reproduction of music in a mobile phone with music reproduction function.

10

MEANS TO ACHIEVE OBJECT

A mobile phone 100 with music reproduction function comprises a communication unit 108 that detects an incoming call from outside, a reproduction unit 106 that reproduces music data, an incoming
15 call processing information storage unit 107 that stores one or more resume methods, and a control unit 103 that determines a readout position of the music data based on a predetermined reproduction resume method stored in the incoming call processing information storage unit 107 after a talk finishes and instructs the reproduction
20 unit 106 to reproduce the music data from the determined readout position.
